Additional intermediates for producing the compounds of the present invention include those of the formula VI:

Novel methods of making the compounds described above are also provided as are novel methods of using the compounds in the inhibition of HIV protease enzyme and pharmaceutical compositions containing the compounds.

The retroviral protease inhibiting compounds of the present invention are prepared as follows. An important intermediate in the preparation of the compounds of this invention are compounds of the formula VII.

VII

Compounds of formula VII, wherein  $R_1$ ,  $R_2$ ,  $R_4$ , Z, a, b, and c are hereinabove defined, are prepared as described below. Commercially available 3-chloro-2-chloromethyl-1-propene is converted into diiodide 102 upon treatment with sodium iodide in acetone.

Commercially available (S)-(-)-4-benzyl-2-oxazolidinone is converted into substituted oxazolidinones of formula 103 upon treatment with base and acid chlorides of the formula  $R_1CH_2COCl$ , wherein  $R_1$  is hereinabove defined, following the methodology of Evans et al., (J.Am.Chem.Soc., 104, 1737-9(1982)).

Other oxazolidinones of the general formula:

in which  $D = (C_1-C_7)\text{alkyl}$ ;  $-(CH_2)_n\text{-phenyl}$ ,  $n = 0-4$ ; E and F are the same or different and are selected from H,  $(C_1-C_7)\text{alkyl}$  and  $-(CH_2)_n\text{-phenyl}$ ,  $n = 0-4$ , are equally effective as alternatives to 103. When D is  $-(CH_2)_n\text{-phenyl}$ , E and F are hydrogen and  $n = 1$ , the compound of formula 103 results.

The anion of 103 is prepared by treatment of 103 with strong base, eq  $NaN(TMS)_2$ , in which TMS = trimethylsilyl, at temperature  $<-70^\circ\text{C}$ . When an excess of compound 102 is allowed to react with the anion of 103 at low temperatures, a compound of formula 104 is produced.

104

When compounds of formula 104 are allowed to react with secondary amines of formula 105, in the presence of a tertiary amine base such as N,N-diisopropylethylamine, compounds of formula V are formed. Treatment of compounds of formula V with hydrogen peroxide and lithium hydroxide produce acids of formula VII. The chemistry used to prepare compounds of formula VII is compatible with a wide variety of  $R_1$ ,  $R_2$ ,  $R_4$  and  $R_5$  groups.

When compounds of formula VII are allowed to react with amines of formula  $R_3NH_2$  where  $R_3$  is defined hereinabove in the presence of BOP, a tertiary amine such as N,N-diisopropylethylamine and optionally HOBT, compounds of formula 107 are produced, where BOP = benzotriazol-1-yloxytris(dimethylamino)phosphonium-hexafluorophosphate and HOBT = 1-hydroxybenzotriazole.

Other methods for formation of amide bonds, including DCC mediated coupling, are applicable, where DCC = 1,3-dicyclohexylcarbodiimide. A wide variety of  $R_3$  groups are compatible with the above chemistry.

Compounds of formula 107, are converted into their corresponding diols 108, upon treatment with osmium tetroxide in the presence of pyridine.

Diols of formula 108, upon treatment with sodium periodate, are converted into intermediate ketones 109, which are reduced upon treatment with sodium borohydride to give alcohols 110.

Pharmaceutically suitable salts include both the metallic (inorganic) salts and organic salts; a list of which is given in Remington's Pharmaceutical Sciences, 17th Edition, pg. 1418 (1985). It is well known to one skilled in the art that an appropriate salt form is chosen based on physical and chemical stability, flowability, hygroscopicity and solubility. Preferred salts of this invention for the reasons cited above include the inorganic salts: hydrochloric, hydrobromic, hydroiodic, phosphoric, nitric or sulfuric; as well as organic salts: acetate or other alkylcarboxylates, benzoate or other arylcarboxylates, citrate, cysteine or other amino acids, fumarate, glycolate, maleate, succinate, tartrate, alkylsulfonate, arylsulfonate, trifluoroacetate or trifluoromethanesulfonate.

109110BIOLOGICAL ACTIVITY

IC<sub>50</sub> values for enzyme inhibition are determined using HIV-1 and Amersham's HIV proteinase [<sup>125</sup>I]-scintillation proximity assay (SPA). The results are given in Table 1.

Amersham's HIV proteinase [<sup>125</sup>I]-SPA system is a commercial assay incorporating the scintillation proximity assay (SPA) principle available from Amersham International PLC, Bucks, England.

The SPA microspheres provided by Amersham have the substrate linked directly to the surface through a streptavidin-biotin link. The substrate is a 12 residue peptide designed specifically for this application utilizing current knowledge of known cleavage sites for the enzyme and analogue substrate studies. The sequence of the substrate is:

AcN-TYR-ARG-ALA-ARG-VAL-PHE-PHE-VAL-ARG-ALA-ALA-LYS-COO

BIOTIN—

The peptide is monoiodinated on the tyrosine residue and biotinylated through the epsilon-NH<sub>2</sub> group on the lysine. It is linked to the SPA bead via a streptavidin-link. The beads are suspended in a buffer consisting of 5mM DTT, 1mM EDTA, 10% w/v glycerol, 0.05% W/v sodium azide, 0.01% v/v Triton X-100 in 25mM sodium citrate buffer pH 5.5.

The enzyme cleaves at the Phe-Phe bond releasing the  $^{125}\text{I}$  fragment from the bead. This event causes the removal of detectable signal from the microsphere. Once the peptide fragment has left the bead it can no longer stimulate the scintillant and the signal therefore is reduced. The rate of reduction in signal is proportional to the activity of the enzyme. The obtained data is used to calculate the  $\text{IC}_{50}$  values found in Table 1.

In Table 2, data is shown for the ability of these compounds to inhibit growth of HIV-1 strain IIIB in T lymphoid MT-2 cell lines. The cell line is challenged by free virions selected to result in 90-95% cell death (CPE) by day 5. The protease inhibitor compound is then added in the stated concentration. After 5 days, the surviving cells are measured using metabolic MTT dye.

As can be seen from the data presented hereinabove in Table 1 and 2, the compounds of the present invention are potent inhibitors of the HIV-1 protease enzyme and thus are useful in treating mammals infected with retroviruses, especially HIV-1. The present invention also includes combinations of the HIV protease inhibitory compounds with one or more other agents useful in the treatment of AIDS.

When the compounds are employed for the above utility, they can be combined with one or more pharmaceutically acceptable carriers, for example, solvents, diluents and the like, and may be administered orally in such form as tablets, capsules, dispersible powders, granules, or suspensions containing, for example, from about 0.05 to 5% of suspending agent, syrups containing, for example, from about 10 to 50% of sugar and elixirs containing, for example, from about 20 to 50% ethanol, and the like, or parenterally in the form of sterile injectable solutions or suspensions containing from about 0.05 to 5% suspending agent

in an isotonic medium. Such pharmaceutical preparations may contain, for example, from about 0.05 up to about 90% of the active ingredient in combination with the carrier, more usually between about 5% and 60% by weight.

An effective amount of compound from 0.2 mg/kg of body weight to 100.0 mg/kg of body weight should be administered one to five times per day via any topical route of administration including but not limited to oral, parenteral (including subcutaneous, intravenous, intramuscular, intrasternal injection or infusion techniques), by inhalation spray, or rectally, in dosage unit formulations containing conventional non-toxic pharmaceutically acceptable carriers, adjuvants and vehicles. It will be understood, however, that the specific dose level and frequency of dosage for any particular patient may be varied and will depend upon a variety of factors including the activity of the specific compound employed, the metabolic stability and length of action of that compound, the age, body weight, general health, sex, diet, mode and time of administration, rate of excretion, drug combination, the severity of the particular condition, and the host undergoing therapy.

These active compounds may be administered orally as well as by intravenous, intramuscular, or subcutaneous routes. Solid carriers include starch, lactose, dicalcium phosphate, microcrystalline cellulose, sucrose and kaolin, while liquid carriers include sterile water, polyethylene glycols, non-ionic surfactants and edible oils such as corn, peanut and sesame oils, as are appropriate to the nature of the active ingredient and the particular form of administration desired. Adjuvants customarily employed in the preparation of pharmaceutical compositions may be advantageously included, such as flavoring agents, coloring agents, preserving agents, and antioxidants, for example, vitamin E, ascorbic acid, BHT and BHA.

The preferred pharmaceutical compositions from the standpoint of ease of preparation and administration are solid compositions, particularly tablets and hard-filled or liquid-filled capsules. Oral administration of the compounds is preferred.

These active compounds may also be administered parenterally or intraperitoneally. Solutions or suspensions of these active compounds as a free base or pharmacologically acceptable salt can be prepared in water suitably mixed with a surfactant such as hydroxypropylcellulose. Dispersions can also be prepared in glycerol, liquid polyethylene glycols and mixtures thereof in oils. Under ordinary conditions of storage and use, these preparations contain a preservative to prevent the growth of microorganisms.

The pharmaceutical forms suitable for injectable use include sterile aqueous solutions or dispersions and sterile powders for the extemporaneous preparation of sterile injectable solutions or dispersions. In all cases, the form must be sterile and must be fluid to the extent that easy syringability exists. It must be stable under the conditions of manufacture and storage and must be preserved against the contaminating action of microorganisms such as bacteria and fungi. The carrier can be a solvent or dispersion medium containing, for example, water, ethanol, polyol (e.g., glycerol, propylene glycol and liquid polyethylene glycol), suitable mixtures thereof, and vegetable oil.

For [3S-[2[alphaS\*(1R\*,2R\*),gammaS\*(or R\*)], 3alpha,4abeta,8abeta]]-N-[1-[[[1H-benzimidazol-2-ylmethyl]amino]carbonyl]-2-methylbutyl]-3-[[[1,1-dimethylethyl]amino]carbonyl]decahydro-gamma-hydroxy-alpha-(phenylmethyl)-2-isoquinolinepentanamide, Example 24B, in an aqueous liposomal formulation, concentrations of >0.13 microgram/ml in plasma are achieved in mice for 2.8 and 4.2 hours following IP injection with doses of 8.3 and 16.6 mg/kg respectively. Concentrations >0.13 microgram /ml of Example 24B in plasma are also maintained for 2 hours following oral administration of a dose of 16.6 mg/kg (Figure 1). Such a concentration (>0.13 microgram/ml) results in a >90% inhibition of HIV-1 strain IIIB viral growth in MT-2 cell lines (Table 2). A suitable aqueous liposomal formulation comprises Egg phosphatidyl glycerol, dimyristoyl phosphatidyl choline, butylated hydroxy toluene, lactose and water.

The invention will be more fully described in conjunction with the following specific examples which are not to be construed as limiting the scope of the invention.
